Overview

1. Framework and Estimator
2. Optimal Bandwidth Selection
3. Optimal Kernel Selection
4. Implementation of the Bandwidth Selection Method
5. Simulation Study
6. Conclusions
Consider the following Stochastic Differential Equation (SDE): \[
dX_t = \mu_t \, dt + \sigma_t \, dB_t
\] (1)
where \( B := \{B_t\}_{t \geq 0} \) is a standard Brownian Motion (BM).

In Financial settings, \( X_t = \log(S_t) \), where \( S_t \) is the price of an asset, and the return of the asset is
\[
\frac{S_{t+\Delta t} - S_t}{S_t} \approx \log(S_{t+\Delta t}) - \log(S_t) = \mu_t \Delta t + \sigma_t (B_{t+\Delta t} - B_t).
\]

Data: equally spaced observations: We observe \( X_{t_i} \) at time \( t_i := t_{i,n} = iT/n, 0 \leq i \leq n \).

Notations:

Data increments: \( \Delta_i X := \Delta_i^n X := X_{t_i} - X_{t_{i-1}} \),

Time increments: \( \Delta := \Delta_n = T/n \).
The Model and the Statistical Problem II

The problem:

To estimate the volatility $\sigma_\tau$ for a fixed $\tau$ based on all observations $X_{t_i}$.

Why do spot volatility estimation matter?

1. Spot volatility $\sigma_\tau$ measures the (local) risk of an asset.
2. Volatility is crucial in asset allocation, option pricing, risk management,…
3. Spot volatility allows to detect patterns of volatility within a certain period of time.
The Idea of Kernel Estimator I

- Start from the Integrated Variance or Quadratic Variation:
  \[ IV_t = [X]_t = \int_0^t \sigma_s^2 ds. \]
- The standard estimator of IV is the Realized Quadratic Variation:
  \[ RV_{t,n} := [\hat{X}]_{t,n} := \sum_{i:t_i \leq t} (\Delta_i^n X)^2 \rightarrow \int_0^t \sigma_s^2 ds, \quad n \rightarrow \infty. \]
- From IV to Spot Vol at \( \tau \): consider the Kernel Weighted Volatility:
  \[ KV_h(\tau) = \int_0^T K_h(s - \tau) \sigma_s^2 ds = \int_0^T K_h(s - \tau) d[X]_s \rightarrow \sigma_\tau^2, \quad h \rightarrow 0. \]

Here, weights are given by the scaled kernel function
\[ K_h(x) := K(x/h)/h \text{ such that } \int K(x)dx = 1. \]
\( K \) is the kernel function and \( h \) is the bandwidth.
The Idea of Kernel Estimator II

- It is then natural to estimate the Kernel Weighted Volatility by the following Kernel Weighted Realized Variation, for given \( h \):

\[
\hat{\sigma}^2_{\tau,n,h} := \int_0^T K_h(s - \tau) d\widehat{[X]}_{s,n} = \sum_{i=1}^n K_h(t_{i-1} - \tau)(\Delta_i^n X)^2
\]

\[
\rightarrow KV_h(\tau), \quad n \to \infty
\]

- For a fixed \( n \), we cannot set \( h \) arbitrarily small.
- Instead, we should carefully select \( h = h_n \).
- Define the MSE of the kernel estimator as

\[
MSE_n(h) = \mathbb{E}[(\hat{\sigma}^2_{\tau} - \sigma^2_{\tau})^2] = \mathbb{E} \left[ \left( \sum_{i=1}^n K_h(t_{i-1} - \tau)(\Delta_i^n X)^2 - \sigma^2_{\tau} \right)^2 \right].
\]

The key problem is:

Choose \( h = h_n \) to minimize \( MSE_n \).
Comparison to Key Related Works I

- Fan and Wang (2008) gives consistency and CLT results but did not consider the problem of bandwidth and kernel selection.

- Kristensen (2010) considers the problem bandwidth selection but under the following relatively strong path-wise assumption:

\[ P - \text{a.e. } \omega : |\sigma_{t+\delta}(\omega) - \sigma_t(\omega)|^2 = L_t(\delta; \omega)\delta^\gamma + o_P(\delta^\nu), \forall t, (\delta \to 0), \]

where \( \gamma \in (0, 2] \) and \( \delta \to L_t(\delta) \) is a slowly varying (random) function at 0 and \( t \to L_t(0) := \lim_{\delta \to 0^+} L_t(\delta) \) is continuous.

- Then, based on a non-leverage assumption, argues that \( \sigma \) can be assumed deterministic.

- Under the latter assumption, proposes

\[ h_{n,\tau}^{opt} = n^{-\frac{1}{\gamma+1}} \left( \frac{2 T \sigma_t^4 \| K^2 \|_1}{\gamma L_\tau(0) \kappa^2(K)} \right)^{\frac{1}{\gamma+1}}, \quad \kappa(K) := \int K(x)xdx \neq 0; \]

Assumption (■) is hard to be verified with explicit \( L_t(0) \in (0, \infty) \).
• Our first assumption is a simplifying non-leverage assumption (also used in Kristensen, 2010):

**Assumption 1**

\((\mu, \sigma) \text{ is independent of } B.\)

• Another assumption is the boundedness of the moments of \(\mu\) and \(\sigma\) up to 4th degree.

**Assumption 2**

There exists \(M_T > 1\) such that \(\mathbb{E}[\mu_t^4 + \sigma_t^4] < M_T\), for all \(0 \leq t \leq T\).
Assumptions on the Volatility Process II

The following is the key assumption that we need for our purpose:

Assumption 3 (∗)

Suppose that the variance process \( V := \{ V_t = \sigma_t^2 : t \geq 0 \} \) satisfies

\[
\mathbb{E}[(V_{t+r} - V_t)(V_{t+s} - V_t)] = L(t)C_\gamma(r, s) + o((r^2 + s^2)^{\gamma/2}), \quad r, s \to 0, \quad (∗)
\]

for some \( \gamma > 0 \) and certain functions \( L : \mathbb{R}_+ \to \mathbb{R}_+ \) and \( C_\gamma : \mathbb{R} \times \mathbb{R} \to \mathbb{R} \) such that \( C_\gamma \) is not identically zero and has the scaling property:

\[
C_\gamma(hr, hs) = h^\gamma C_\gamma(r, s), \quad \text{for } r, s \in \mathbb{R}, h \in \mathbb{R}_+.
\]

Hereafter, we denote \( C_\gamma(r, s; t) = L(t)C_\gamma(r, s) \), which can be interpreted as the “local covariance function” of the variance process. \( V \)
Assumptions on the Volatility Process III

- Two useful propositions directly follow:

**Proposition 1**

*Under the Key Assumption (⋆), the following two assertions hold:*

- The $\gamma$ and $C_\gamma(r, s; t) := L(t)C_\gamma(r, s)$ are unique.

- $C_\gamma(\cdot, \cdot)$ is integrally non-negative definite. That is, for any integrable $K : \mathbb{R} \to \mathbb{R}$, we have

  $$\int\int K(x)K(y)C_\gamma(x, y)dxdy \geq 0.$$  

**Remark:** In that case that

$$\int\int K(x)K(y)C_\gamma(x, y)dxdy > 0,$$

for any integrable nonzero $K : \mathbb{R} \to \mathbb{R}$, we say that $C_\gamma(x, y)$ is integrally positive definite.
The first class of volatility processes that satisfy the Key Assumption (⋆),

$$\mathbb{E}[(V_{t+r} - V_t)(V_{t+s} - V_t)] = L(t)C_\gamma(r, s) + o((r^2 + s^2)^{\gamma/2}),$$

is a deterministic and smooth volatility:

**Lemma 1**

Let \( f(t), 0 \leq t \leq T, \) be differentiable at \( t \) and \( f'(t) \neq 0. \) Then, the squared volatility process \( V_t = \sigma_t^2 = f(t) \) satisfies (⋆) with

\[ \gamma = 2, \quad L(t) = (f'(t))^2, \quad C_\gamma(r, s) = rs. \]
We consider a standard SDE driven by BM.

In Financial Mathematics, this is one of the most important way to generalize Black-Scholes model to non-constant volatility.

**Lemma 2**

Consider a stochastic process $V_t = \sigma^2(t)$ that satisfies

$$dV_t = f(t)dt + g(t)dW_t, \quad t \in [0, T],$$

where $W$ is a standard Brownian Motion. Assume that $\mathbb{E}[f^2(t)] < M$ for $t \in [0, T]$ and $\mathbb{E}[g^2(t)]$ is continuous for $t \in [0, T]$. Then, the Key Assumption (⋆) is satisfied with $\gamma = 1$, $L(t) = \mathbb{E}[g^2(t)]$, and the function

$$C_\gamma(r, s) := \min\{|r|, |s|\}1_{\{rs \geq 0\}} = \mathbb{E}[(W_{t+r} - W_t)(W_{t+s} - W_t)],$$

which is furthermore integrally positive definite.
Heston Model

- One of the most widely used stochastic volatility models in Finance is

\[
\begin{align*}
    dX_t &= \mu_t \, dt + \sqrt{V_t} \, dB_t, \\
    dV_t &= \kappa (\theta - V_t) \, dt + \xi \sqrt{V_t} \, dW_t,
\end{align*}
\]

where parameters are restricted to \(2\kappa \theta > \xi^2\), s.t. \(V_t = \sigma_t^2\) is always positive.

- The volatility process has the so-called mean reverting property;

- The parameters:
  - \(\theta\) is the long-run variance level;
  - \(\kappa\) is the speed at which \(V_t\) reverts to \(\theta\);
  - \(\xi\) is the volatility of volatility.

- By the previous lemma, Assumption 3 is satisfied with

\[
\gamma = 1, \quad L(t) = \xi^2 \mathbb{E}(V_t), \quad C_{\gamma}(r, s) = \min\{|r|, |s|\} 1_{\{rs \geq 0\}}.
\]
Lemma 3

Consider a process \( \{ Y_t^H \}_{t \geq 0} \) that satisfies

\[
Y_t^H = \int_{-\infty}^{t} f(u) dB_u^H,
\]

where \( \{ B_u^H \}_{u \in \mathbb{R}} \) is a (two-sided) fractional Brownian motion with Hurst parameter \( H \in (\frac{1}{2}, 1) \) and \( f(u) \) is a continuous deterministic function s.t.

\[
\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(u)f(v)|u - v|^{2H-2}dudv < \infty.
\]

Then, the process \( Y_t^H \) and \( \exp(Y_t^H) \) satisfies the key Assumption (⋆) with \( \gamma = 2H \in (1, 2) \) and

\[
C_\gamma(r, s) := \mathbb{E}[B_r^H B_s^H] = \frac{1}{2}(|r|^{2H} + |s|^{2H} - |r - s|^{2H}), \quad r, s \in \mathbb{R}.
\]
Conditions on Kernel Function

Assumption 4

Given $\gamma$ and $C_\gamma$ as defined in our key Assumption (⋆), we suppose that the kernel function $K : \mathbb{R} \to \mathbb{R}$ satisfies the following:

1. $\int K(x)dx = 1$,
2. $K(x)$ is piece-wise continuously differentiable,
3. $\int |K(x)||x|^\gamma dx < \infty$, $K(x)x^{\gamma+1} \to 0$, $|x| \to \infty$,
4. $\iint K(x)K(y)C_\gamma(x, y)dxdy > 0$.

Notice that the condition (4) above does not put substantial restriction on $K$ since $C_\gamma$ is already integrally non-negative definite.

6 Conclusions
Approximation of MSE

The idea is to approximate MSE by leading order infinitesimals:

$$\text{MSE} = \mathbb{E} \left[ \left( \sum_{i=1}^{n} K_h(t_{i-1} - \tau)(\Delta_i X)^2 - \sigma^2_\tau \right)^2 \right]$$

$$= 2 \sum_{i=1}^{n} K_h^2(t_{i-1} - \tau) \mathbb{E} \left[ \left( \int_{t_{i-1}}^{t_i} \sigma^2_t dt \right)^2 \right]$$

$$+ \sum_{i=1}^{n} \sum_{j=1}^{n} K_h(t_{i-1} - \tau) K_h(t_{j-1} - \tau)$$

$$\times \int_{t_{i-1}}^{t_i} \int_{t_{j-1}}^{t_j} \mathbb{E}[\left( \sigma^2_t - \sigma^2_\tau \right) \left( \sigma^2_s - \sigma^2_\tau \right)] dt ds$$

$$+ o\left( \frac{\Delta}{h} \right) + o(h^\gamma)$$
We have the following first order approximation of the MSE:

**Theorem 1 (F-L & Li 2016)**

For $\mu$ and $\sigma$ satisfying Assumptions 1, 2 and 3 and a kernel function $K$ satisfying Assumption 4, we have, for any $\tau \in (0, T)$,

$$MSE_{\tau,n}(h) = \mathbb{E} \left[ (\hat{\sigma}_{\tau,n,h}^2 - \sigma_{\tau}^2)^2 \right]$$

$$= 2 \frac{\Delta}{h} \mathbb{E}[\sigma_{\tau}^4] \int K^2(x)dx + h^\gamma L(\tau) \int \int K(x)K(y)C_\gamma(x,y)dxdy$$

$$+ o\left(\frac{\Delta}{h}\right) + o(h^\gamma),$$

where $C(x, y; t) = L(t)C_\gamma(x, y)$ is the “local covariance function” of $V_t = \sigma_t^2$ as defined by the Key Assumption ($\star$).
Consider the approximated MSE of the kernel estimator:

$$\text{MSE}_{\tau, n}(h) := 2 \frac{\Delta}{h} \mathbb{E}[\sigma^4_{\tau}] \| K^2 \|_1 + h^\gamma L(\tau) \int \int K(x)K(y)C_\gamma(x, y)dx dy$$

Note that $2 \mathbb{E}[\sigma^4_{\tau}] \| K^2 \|_1 > 0$.

Furthermore, by the previous assumptions, $L(\tau) \int \int K(x)K(y)C_\gamma(x, y)dx dy > 0$.

Taking the derivative of $\text{MSE}_{\tau, n}(h)$ w.r.t. $h$, we then have the following:
Proposition 2

The approximated optimal bandwidth, denoted by $h_{n,\tau}^{a,\text{opt}}$, which, by definition, minimizes the approximated $MSE_n^a(h)$, is given by

$$h_{n,\tau}^{a,\text{opt}} = n^{-1/(\gamma+1)} \left[ \frac{2 T E[\sigma^4_{\tau}] \| K^2 \|_1}{\gamma L(\tau) \int \int K(x)K(y)C_\gamma(x, y) \, dx \, dy} \right]^{1/(\gamma+1)},$$

while the resulting minima value of the approximated $MSE$ is given by

$$MSE_{n}^{a,\text{opt}} = n^{-\gamma/(1+\gamma)} \left( 1 + \frac{1}{\gamma} \right) (2 T E[\sigma^4_{\tau}] \| K^2 \|_1)^{\gamma/(1+\gamma)} \times \left( \gamma L(\tau) \int \int K(x)K(y)C_\gamma(x, y) \, dx \, dy \right)^{1/(1+\gamma)}.$$
Examples

- When $\sigma_t^2 = f(t)$ is deterministic and smooth ($\gamma = 2$, $L(t) = (f'(t))^2$, and $C_\gamma(r, s) = rs$), we recover Kristensen (2010):

$$h_{n, \tau}^{opt} = n^{-\frac{1}{\gamma+1}} \left( \frac{2f(t)^2 \| K^2 \|_1}{\gamma(f'(\tau))^2 \kappa^2(K)} \right)^{\frac{1}{\gamma+1}}, \quad \kappa(K) := \int K(x)xdx \neq 0;$$

If $\int K(x)xdx = 0$, one can improve the rate of convergence of the MSE;

- For B.M.-driven volatilities $d\sigma_t^2 = f(t)dt + g(t)dW_t$,

$$h_{n, \tau}^{a, opt} = n^{-1/2} \left[ \frac{2 T \mathbb{E}[\sigma_T^4] \| K^2 \|_1}{\mathbb{E} [g^2(\tau)] \kappa_{BM}(K)} \right]^{1/2},$$

$$\kappa_{BM}(K) = \int_0^\infty \int_0^\infty [K(x)K(y) + K(-x)K(-y)] \min(x, y) dx dy,$$

where the latter is always positive (regardless $K \neq 0$);

- The rate of convergence of the MSE, $n^{-1/2}$, cannot be improved;
In the case that we consider the Integrated MSE (IMSE)

$$\text{IMSE}_n(h) = \int_0^T \mathbb{E}[(\hat{\sigma}_{\tau,n}^2 - \sigma_{\tau}^2)^2] d\tau$$

the optimal (uniform) bandwidth takes the form:

$$h_{n,\text{opt}} = n^{-1/(\gamma+1)} \left[ \frac{2T \int_0^T \mathbb{E}[\sigma_{\tau}^4] d\tau \| K^2 \|_1}{\gamma \int_0^T L(\tau) d\tau \int \int K(x)K(y)C_{\gamma}(x,y) dx dy} \right]^{1/(\gamma+1)}.$$
The questions now are:

- whether our approximated optimal bandwidth yields good approximation for the true optimal bandwidth.
- whether the kernel estimator with such approximated optimal bandwidth performs good.

Formally, consider

- the true MSE: $MSE_n(h) = \mathbb{E}[(\hat{\sigma}_{\tau,n,h}^2 - \sigma^2)^2]$.
- A true optimal bandwidth $h_n^{opt} = \arg \min_{h \in \mathbb{R}_+} MSE_n(h)$
- The approximated optimal bandwidth: $h_n^{a,opt}$. 
Theorem 2 (F-L & Li 2016)

For \( \mu \) and \( \sigma \) satisfying Assumptions 1, 2, 3 and a kernel function \( K \) satisfying Assumption 4, we have

\[
    h_{n,\text{opt}}^a = h_{n,\text{opt}} + o(h_{n,\text{opt}}),
\]

\[
    \text{MSE}_n(h_{n,\text{opt}}^a) = \text{MSE}_n(h_{n,\text{opt}}) + o(\text{MSE}_n(h_{n,\text{opt}})).
\]
1. Framework and Estimator

2. Optimal Bandwidth Selection

3. Optimal Kernel Selection

4. Implementation of the Bandwidth Selection Method

5. Simulation Study

6. Conclusions
BM Volatility Case I

- Recall the approximated optimal MSE:

\[
\text{MSE}_{n,\text{opt}}^a = n^{\gamma/(1+\gamma)} \left(1 + \frac{1}{\gamma}\right) \left(2 T \mathbb{E}[\sigma_\tau^4] \int K^2(x) dx\right)^{\gamma/(1+\gamma)} \times \left(\gamma L(\tau) \int \int K(x)K(y)C_\gamma(x,y) dx dy\right)^{1/(1+\gamma)}.
\]

- In the BM case, if we try to minimize this approximated optimal MSE\(^{a,\text{opt}}(K)\) over \(K\), we need to minimize the following objective function \(I(K)\):

\[
I(K) = \int K^2(x) dx \int_0^\infty \int_0^\infty [K(x)K(y) + K(-x)K(-y)] \min(x, y) dx dy,
\]

with the restriction \(\int K(x) dx = 1\).
By solving the optimization problem, we obtain the following theorem:

**Theorem 3 (F-L & Li 2016)**

*With all previous assumptions, in the case of BM type volatility, the optimal kernel function is given by $K^{\text{opt}}(x) = \frac{1}{2} e^{-|x|}$, $x \in \mathbb{R}$.*

We now do some calculations and demonstrate to what extent the exponential kernel decrease the MSE.

**Example 3.1**

*As seen before, $\text{MSE}_n^{a,\text{opt}}(K) = C \sqrt{I(K)}$ width a constant $C$ that does not depend on $K$. Then, we can see that $\sqrt{I(\frac{1}{2} e^{-|x|})} = \frac{1}{4} = 0.25$. Some simple calculations show that $\sqrt{I(\frac{1}{2} 1_{\{|x|<1\}})} = \frac{1}{2\sqrt{3}} \approx 0.2887$, $\sqrt{I(|1-x| 1_{\{|x|<1\}})} = \frac{1}{\sqrt{15}} \approx 0.2582$.***
Recall that

\[ \hat{\sigma}^2_T = \hat{\sigma}^2_{T,n,h} := \sum_{j=1}^{n} K_h(t_{j-1} - \tau)(\Delta^n_j X)^2 \]

In general, to find \( \hat{\sigma}_{t_i} \) for one fixed \( i \), we need a time complexity of \( O(n) \) or \( O(nh) \) for a kernel function with unbounded or bounded support, respectively.

So, to find \( \hat{\sigma}_{t_i} \) for all \( 0 \leq i \leq n \), we need a time complexity of \( O(n^2) \) or \( O(n^2 h) \), respectively.

The best time complexity of \( O(n^{2-1/(\gamma+1)}) \), with optimal bandwidth, is not be efficient for high frequency data.

But, the rate can be improved for uniform and exponential kernels using a type of fast implementation algorithm.
For the uniform kernel, we have

$$\hat{\sigma}_{t_{i+1}, \text{unif}}^2 = \hat{\sigma}_{t_i, \text{unif}}^2 + \frac{1}{2h} (\Delta_k X)^2 - \frac{1}{2h} (\Delta_j X)^2$$

where $k$ and $j$ satisfies

$$k = \min\{l : t_{l-1} > t_i + h\}, \quad j = \max\{l : t_{l-1} \geq t_i - h\}.$$ 

The time complexity to compute $\hat{\sigma}_{t_i}$ for all $0 \leq i \leq n$ is $O(n)$ vs. $O(n^{2-1/(\gamma+1)})$.
For exponential kernel, we use the following notation:

\[
\hat{\sigma}_{t_i,-}^2 = \sum_{j<i} K_h(t_{j-1} - t_i)(\Delta_j X)^2, \\
\hat{\sigma}_{t_i,+}^2 = \sum_{j\geq i+1} K_h(t_{j-1} - t_i)(\Delta_j X)^2
\]

Note that \(\hat{\sigma}_{t_i,\text{exp}}^2 = \sum_j K_h(t_{j-1} - t_i)(\Delta_j X)^2\) can be written as

\[
\hat{\sigma}_{t_i,\text{exp}}^2 = \hat{\sigma}_{t_i,+}^2 + \hat{\sigma}_{t_i,-}^2 + K_h(h)(\Delta_i X)^2
\]

We can then use the following recurrent algorithm:

\[
\hat{\sigma}_{t_{i+1},-}^2 = e^{-\Delta/h} \left[ \hat{\sigma}_{t_i,-}^2 + K_h(h)(\Delta_i X)^2 \right] \\
\hat{\sigma}_{t_{i+1},+}^2 = e^{\Delta/h} \left[ \hat{\sigma}_{t_i,+}^2 - K_h(0)(\Delta_{i+1} X)^2 \right]
\]

The time complexity is again \(O(n)\).

2 Optimal Bandwidth Selection

3 Optimal Kernel Selection

4 Implementation of the Bandwidth Selection Method

5 Simulation Study

6 Conclusions
Generally, two types of bandwidth selection methods: plug-in type and cross-validation methods.

Cross-validation methods:
2. Disadvantages: time consuming, hard to find initial value and implement the involved optimization algorithm.

Plug-in type methods:
1. Advantages: always faster and usually better accuracy.
2. Disadvantages: less general.
In Kristensen (2010), a leave-one-out cross validation method is proposed.

Recall that, therein, $\sigma$ is assumed to be deterministic and satisfy a Hölder continuity condition.

The idea is to consider the Integrated Squared Error:
$$ISE(h) = \int_{T_l}^{T_r} (\sigma^2_t - \hat{\sigma}^2_{t,h})^2 dt, \text{ for } 0 < T_l < T_r < T.$$  

An estimator of $ISE$ is
$$\hat{ISE}(h) = \sum_{i=1}^{n} 1\{T_l < t_{i-1} < T_r\} \left[ \frac{(\Delta_i X)^2}{\Delta} - \hat{\sigma}^2_{-i,t_i} \right]^2,$$

where $\hat{\sigma}^2_{-i,t_i} = \sum_{j \neq i} K_h(t_{i-1} - t_i)(\Delta_j X)^2$ is the leave-one-out estimator.

Now find $h^{opt} = \arg\min_{h \in \mathbb{R}^+} \hat{ISE}(h)$.

This result in a numerical optimization problem.
The idea of plug-in bandwidth selection is to use the explicit approximated optimal bandwidth we obtained and estimate all the parameters encountered.

We consider the BM type volatility processes:
\[ dV_t = f(t)dt + g(t)dW_t, \]
in which case \( \gamma = 1 \) and \( C_1(r, s) = \min \{|r|, |s|\}1_{\{rs>0\}}. \)

The approximated optimal bandwidth is then given by
\[
h_{n,\text{opt}}^a = \left[ \frac{2T \mathbb{E}[\sigma_\tau^4] \int K^2(x)dx}{nL(\tau) \int \int K(x)K(y)C_1(x, y)dxdy} \right]^{1/2}. \]

We need to estimate \( \mathbb{E}[\sigma_\tau^4] \) and \( L(\tau) = \mathbb{E}[g^2(\tau)]. \)

Or we can estimate \( \int_0^T \mathbb{E}[\sigma_\tau^4]d\tau \) and \( \int_0^T L(\tau)d\tau = \int_0^T \mathbb{E}[g^2(\tau)]d\tau \) in the IMSE or stationary cases.
Recall the dynamic of Heston Model:

\[ dX_t = \mu_t dt + \sqrt{V_t} dB_t, \]
\[ dV_t = \kappa(\theta - V_t) dt + \xi \sqrt{V_t} dW_t. \]

If we assume a Heston Model, the optimal bandwidth becomes

\[ h_{n,\text{opt}}^a = \left[ \frac{2 T \mathbb{E}[\sigma_T^4] \int K^2(x) dx}{n \xi^2 \mathbb{E}[\sigma_T^2] \iint K(x)K(y)C_1(x,y) dx dy} \right]^{1/2}. \]

Although \( \mathbb{E}[\sigma_T^4] \) and \( \mathbb{E}[\sigma_T^2] \) are not available, it is natural to use \( \hat{\sigma}_T^4 \) and \( \hat{\sigma}_T^2 \) as their estimators.

Since \( [V]_T = \xi^2 [X]_T \), an estimator of \( \xi \) is given by

\[ \hat{\xi}^2 = \frac{\sum_{i=1}^{[n/K]} \left( \hat{\sigma}_{t_{Ki}}^2 - \hat{\sigma}_{t_{K(i-1)}}^2 \right)^2}{\sum_{i=1}^{n} (\Delta_i^n X)^2}, \]

where \( K \) can be chosen to be \( K \approx n^{2/3} \), for example.
If we assume a general Itô processes (say, \( dV_t = f(t)dt + g(t)dW_t \)), the Integrated Volatility of Volatility

\[ IVV = \int_0^T L(t)dt = \int_0^T \mathbb{E}[g^2(t)]dt \]

can be estimated by

\[
\hat{IVV} = \sum_{i=1}^{[n/K]} \left( \hat{\sigma}_{tK_i}^2 - \hat{\sigma}_{tK(i-1)}^2 \right)^2 , \tag{4}
\]

for some suitable \( K \). Therefore, the final bandwidth can be given by:

\[
h_{n, opt}^a = \left[ \frac{2 T \hat{IV}^2 \int K^2(x)dx}{n \hat{IVV} \int \int K(x)K(y)C_1(x, y)dxdy} \right]^{1/2} ,
\]

where \( \hat{IV}^2 = \frac{1}{3\Delta} \sum_{i=1}^{n} (\Delta_i X)^4 \) is the realized quartic variation and \( \hat{IVV} \) is given by (4).
The two estimators of the optimal bandwidth involves the estimation of spot volatility, which we do not know in advance, so we consider the following iterative algorithm:

**The Iterative Plug-in Bandwidth Selection Algorithm:**

**Data:** \( \Delta^n X = X_\Delta - X_0, \ldots, \Delta^n X = X_{n\Delta} - X_{(n-1)\Delta} \)

Set initial values for \( h \) or \( h_{t_i} \);

**while Stopping criteria not met do**

Find an estimation of spot volatility on all the grid points:

\[ \hat{\sigma}_{t_i}^2 \] based on previous bandwidth \( h \) or \( h_{t_i} \);

Update the bandwidth \( h \) or \( h_{t_i} \) based on the new estimation of spot volatility.

**end**

In reality, one or two iterations are enough for satisfactory result, even with bad initial guess.

More iterations do not generally improve the result.

Optimal Bandwidth Selection

Optimal Kernel Selection

Implementation of the Bandwidth Selection Method

Simulation Study

Conclusions
We consider Heston model with the following parameter:

1. 1 year time period, 252 trading days, 6.5 hours each data, minute data.
2. \( \mu_t \equiv 0.05, \sigma_0 = 0.2, \kappa = 5, \theta = 0.2, \xi = 0.5. \)
3. The leverage coefficient \( dB_t \cdot dW_t = \rho dt \) is taken to be either \( \rho = 0 \) or \( \rho = -0.5. \)

First, we compare different kernel functions. We consider five different kernels:

\[
K_1(x) = \frac{1}{2} e^{-|x|}, \quad K_2(x) = \frac{|x|}{x^4 + 2x^2 + 1}, \quad K_3(x) = \frac{1}{2} 1_{\{|x|<1\}}
\]

\[
K_4(x) = |1 - x| 1_{\{|x|<1\}}, \quad K_5(x) = \frac{3}{4}(1 - x^2) 1_{\{|x|<1\}}
\]

The first kernel is the optimal kernel we obtained previously.

The second one is another kernel with infinite domain.
Simulation Study II

- The third, fourth and fifth kernel are finite domain kernel with different order of polynomial.
- The fifth kernel is the so called Epanechnikov kernel that Kristensen (2010) claims to be optimal in the deterministic case.
- In the following table, we only estimate the volatility at $t = \frac{3}{4}$. We see that exponential kernel outperforms other kernel functions.

<table>
<thead>
<tr>
<th>Kernel</th>
<th>$\text{MSE}(\rho = 0)$</th>
<th>$\text{MSE}(\rho = -0.5)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$K_1$</td>
<td>1.1000e-05</td>
<td>1.1569e-05</td>
</tr>
<tr>
<td>$K_2$</td>
<td>1.1976e-05</td>
<td>1.3064e-05</td>
</tr>
<tr>
<td>$K_3$</td>
<td>1.2242e-05</td>
<td>1.3501e-05</td>
</tr>
<tr>
<td>$K_4$</td>
<td>1.1154e-05</td>
<td>1.2037e-05</td>
</tr>
<tr>
<td>$K_5$</td>
<td>1.1420e-05</td>
<td>1.2427e-05</td>
</tr>
</tbody>
</table>
Now we compare the following bandwidth (bw) selection methods for an exponential kernel function:

1. Cross-validation method proposed by Kristensen.
2. Optimal uniform bandwidth selection with 0, 1 and 2 iterations.
3. Optimal spot bandwidth selection for 0, 1 and 2 iterations.

In the following, we consider the approximated integrated MSE $\sum_i (\hat{\sigma}_{t_i}^2 - \sigma_{t_i}^2)^2$ for each method:

<table>
<thead>
<tr>
<th>Method</th>
<th>$\text{MSE}(\rho = 0)$</th>
<th>$\text{MSE}(\rho = -0.5)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cross-Validation</td>
<td>0.4465</td>
<td>0.4196</td>
</tr>
<tr>
<td>Uniform bw $h$, no iteration</td>
<td>0.4567</td>
<td>0.4342</td>
</tr>
<tr>
<td>Uniform bw $h$, 1 iteration</td>
<td>0.4571</td>
<td>0.4339</td>
</tr>
<tr>
<td>Uniform bw $h$, 2 iteration</td>
<td>0.4575</td>
<td>0.4342</td>
</tr>
<tr>
<td>Spot bw $h$, no iteration</td>
<td>0.4439</td>
<td>0.4230</td>
</tr>
<tr>
<td>Spot bw $h$, 1 iteration</td>
<td>0.4422</td>
<td>0.4211</td>
</tr>
<tr>
<td>Spot bw $h$, 2 iteration</td>
<td>0.4423</td>
<td>0.4211</td>
</tr>
</tbody>
</table>

5 Simulation Study

6 Conclusions
Conclusions

1. A new theory for optimal bandwidth selection is put forward under a key assumption on the local covariance of the variance process.

2. The considered framework covers several key models in the literature including volatility models driven by BM and fBM.

3. Our results show that earlier optimal bandwidth selection methods, obtained under a deterministic volatility assumption, are not valid in a stochastic volatility setting.

4. The problem of optimal kernel selection is also considered: it is shown that an exponential kernel is the optimal kernel function for B.M.-driven volatility models.

5. Fast iterated plug-in type algorithms are also devised as a way to implement the proposed optimal selection methods.
